**Tips for electrostatic sprayer system success**

**Electrostatic technology in healthcare**

Electrostatic spray technology is an exciting new application in surface disinfection. Particularly given the COVID-19 pandemic, this is now a quickly growing area, and there is a lot of information out there, it may seem challenging to adopt this new technology as part of your disinfection protocol. But we’re here to help. Here are some tips to help you make sure that the electrostatic sprayer system (ESS) is a success in your healthcare facility.

**Education is key**

ESS are available in a range of formats, including carts, backpacks, and handheld systems, which can be cored or cordless. The type of space you will be disinfecting with the ESS can help you decide on which format is best for your facility – or if you require more than one type of ESS. For example, if you have a large space to disinfect, and ergonomics is a factor, you might choose a cart format. If you need to navigate a crowded space, and would enjoy hands-free mobility, you could consider a backpack format ESS. If you are disinfecting smaller areas and need mobility, the convenience of a handheld system may be right for you.

Once you have selected a system, you can also access online training or educational materials to help train operators in the proper use of the ESS. Many manufacturers of ESS systems or manufacturers of disinfectants designed for use with ESS offer these resources - do check them out!

**Select your disinfectant based on area type**

In healthcare settings there are a number of different areas where you can use an electrostatic sprayer, including patient rooms, lobbies and waiting rooms, and the cafeteria and kitchen. Once you have identified the list of disinfectants that are Health Canada-approved for use with an ESS, consider using more than one product based on the disinfection needs of each of these areas. For example, a sporidical product can be used where *C. difficile* spore is a concern, a product designed to be safe on food contact surfaces in the cafeteria, or a more general disinfectant for the lobby or waiting rooms.

**Develop a protocol for ESS**

A clear and easy-to-understand protocol can help ensure that ESS is successful in your facility. When setting up your protocol, consider the following:

- Ensure that you have an adequate supply of the appropriate personal protective equipment (PPE) for your ESS operators. You can check the PPE requirements based on the product label, safety data sheet (SDS) and WHMIS label of the disinfectant.
- It is not recommended to use the ESS while room occupants are present. Check the contact time and reentry time requirements to protect bystanders.
- Always remove visible soil before disinfecting a surface using your ESS. If there is no visible soil, the ESS can be used for one-step disinfection.

**For best results: Follow a spraying strategy**

- Electrostatic spray is attracted to surfaces and objects, but for best results direct the spray at your target surfaces, not just the air.
- Check the instructions on your ESS to identify how far away you should stand from the surface you are spraying for best results – this is different for every type of sprayer. You want surfaces to be visibly wet for the appropriate contact time for your disinfectant.
- Follow a pattern when you spray the room so you don’t miss spots on the surface. Spray slowly in a side-to-side motion and work from top to bottom to ensure complete coverage.
- Start in a spot farthest from the door and work back to the door in the room you are spraying.
- Check for surface compatibility before spraying. You may want to wipe down surfaces such as glass or electronics after the contact time has been achieved to remove visible residue.

**CloroxPro® has a range of chemistries approved for use in ESS**

Clorox Healthcare® Spore Defense™ Cleaner Disinfectant (DIN: 02494663) formula contains a low level of bleach (0.25% sodium hypochlorite). Spore Defense™ kills influenza, norovirus, VRE, MRSA, and SARS-CoV-2 in 1 minute, and *C. difficile* in 5 minutes. The non-corrosive, non-abrasive formula is compatible with a wide variety of hard surfaces in healthcare facilities and can be used even in patient settings like isolation areas, emergency rooms, patient rooms, restrooms, patient transport equipment and emergency vehicles.

A SUPERIOR HEALTHCARE DISINFECTION EXPERIENCE

SteraMist® ionized Hydrogen Peroxide (IHP™) is a natural disinfection that requires no wiping or rinsing, reaching every corner of your facility for fast, incredible results.

ELIMINATES PATHOGENS:
- Emerging Pathogens & SARS-CoV-2 Coronavirus
- C. difficile & C. auris
- Norovirus & MRSA
- Influenza A
- ...and many more!

PERFECT FOR ANY AREA:
- Surgical Areas
- Staff Rooms & Desks
- Waiting Rooms & Reception
- Emergency Rooms
- Patient Rooms
- ...and so much more!

STERAPAK
- Back-Mounted Unit for Enhanced Maneuverability
- Battery & Direct Power Operation
- Portable for Use in Areas of Any Size

SURFACE UNIT
- Portable Design and Easy-to-Store
- Direct Power Ensures Added Endurance
- Compact Case for Easy Storage

TOTAL DISINFECTION CART
- Perfect for Facilities of Any Size
- Designed for Your Surface Unit
- Easily Store Critical Accessories

ASEPT.1X Max
made for automatic disinfection

automatic | safe | revolutionary

ASEPT.1X Max disinfects 99.99% of contaminants such as VRE, C.difficile, MRSA and SAR-COV-2 virus, by sterilizing the most commonly touched areas.

Completely automated, the ASEPT.1X Max unit includes the following safety features: infrared motion sensors (PIR) and magnetic door detector set. This allows the unit to only operate when no one is in the room, for 5-minute disinfection cycles after each use.
Zone in on zero harm

With Medline as your trusted healthcare supply partner, you will be best equipped to manage your facility’s infection control needs by having easy access to the right products, at the right time, supported with the right expertise.

Every day, you are challenged to reach “zero harm”.

Medline offers best practice guidance to promote reduction in variation, education & training, and a system of products to support best practices that can minimize the spreading of pathogens.

When it comes to infection control systems, Medline has you covered. Every Time. Front to Back. Top to Bottom.

Discordant COVID-19 PCR test results and the implications in long-term care

James Ayukekbong, BMLS, MSc, PhD, CIC
Editor-in-Chief, Canadian Journal of Infection Control

SARS-CoV-2, the causative agent of Coronavirus Disease 2019 (COVID-19) has infected over 247 million people worldwide, and is responsible for over 5 million deaths (as of November 2, 2021) [1]. The brunt of the disease has been felt more among the elderly, especially those living in long-term care homes. As public health authorities battle with outbreak management, a clear definition of what constitutes an outbreak is essential. Often, outbreak declarations are triggered by two or more laboratory-confirmed COVID-19 cases with an epidemiological link within a 14-day period where both cases could have reasonably acquired their infection in the same setting [2, 3]. Although this definition seems scientifically appealing, outbreak management and the care of residents may be affected if laboratory test results are not indeed confirmed, or if results appear to be discordant. An example of a discordant result is when a specimen from an individual tests positive, and a subsequent specimen or repeat tests from the same person within the same timeframe using the same or a different assay gives negative results [4, 5].

To understand the concept of discordant results, that is false-positive or false-negative Polymerase Chain Reaction (PCR) tests, it is important to understand the principle behind PCR. Basically, the COVID-19 PCR test is meant to detect the genetic material (ribonucleic acid or RNA) of SARS-CoV-2 virus in a specimen [6]. The test starts with RNA extraction from a respiratory specimen followed by reverse transcription to complementary deoxyribonucleic acid (cDNA), which is then amplified using oligonucleotide primers and fluorescently labelled probe(s) specific to region(s) of the SARS-CoV-2 genome [7, 8]. If SARS-CoV-2 RNA is present in the sample, these oligonucleotide primers attach themselves to target sections of the cDNA. Through a thermocycling reaction, identical copies of the target sections of cDNA are created. It should be noted that PCR assays have cut-off points (the number of cycles it runs), and different laboratories may set different cut-off values. Typically, a standard real time PCR set-up usually goes through about 40 cycles.

As new copies of the viral DNA sections are built, the fluorescent probes attach to the DNA strands and then release a fluorescent signal, which is measured in real time. The number of amplification cycles required to create enough copies of the viral RNA to be detected is called the cycle threshold or Ct value. The more RNA that is present in the specimen, the fewer cycles are required for the signal to reach the detection threshold (low Ct value, e.g., Ct<30). The less RNA present in the specimen, the more cycles are required. So, a low Ct value corresponds to a high viral load, while a high Ct value corresponds to a low viral load. For example, the cut-off point for a positive result for public health Ontario laboratories is 38 cycles. This means that if the virus is detected at or before 38 cycles are completed, then the test is considered positive. The cut-off point for a negative result is 40 cycles. If the virus is detected between 38 and 40 cycles, then it is considered as indeterminate or inconclusive [9]. Also, because the test does not detect live virus (only viral nucleic acid), the test could detect RNA, not just from an individual who has an active infection, but also in persons who may be shedding the viral particles from a recent infection and may no longer be infectious [8].

With the understanding of the principle behind PCR testing, it is important to mention that false-positive PCR results could occur due to human or analytical errors. From a human error perspective, samples can get mixed up, software glitches can produce erroneous interpretations of test results, and mistakes can be made when entering or communicating results [10]. From an analytical standpoint, cross-contamination of samples during collection, pipetting, or processing may generate false-positive results [11]. The propensity of false-positive results has also been linked to increased frequency of asymptomatic testing in settings of low SARS-CoV-2 incidence, or low pre-test probability [12].

On the other hand, false-negative results can occur for numerous reasons, including inappropriate specimen type, suboptimal specimen collection, testing too early in the disease process (low viral load), or low analytic sensitivity [13, 14]. Other factors such as the quality of the RNA extracted from the swabs, degradation of purified RNA, the presence of RT-PCR inhibitors, or genomic mutations may cause false-negative results [15].

As discussed above, considering the fact that PCR diagnostic

Conflicts of Interest: None to disclose.
Acknowledgements: Sincere thanks to Barb Catt, Past President of IPAC Canada and Dr. Devon Metcalf, Associate Editor of the Canadian Journal of Infection Control for their review and useful suggestions.
performance, including analytical sensitivity and specificity may vary, it is essential that laboratory results are verified before confirmed outbreak declarations are made.

In this Editorial, I would like to focus on false-positive results as every false-positive test has direct negative consequences on outbreak management and the care of residents in long-term care facilities. Staff with false-positive test results and their close contacts are excluded from work, and this can lead to staffing shortages. False-positive results may also lead to unnecessary testing of residents and placement on additional precautions (droplet/contact precautions) for up to 14 days due to the perceived exposure. Unnecessary isolation can worsen loneliness, psychological distress and overall mental health of residents [16]. Misdiagnosis can also result in stigmatization and the fear of infecting others, as well as unnecessary restriction of visitation to the home, and leave of absence of residents.

Besides causing an increase in operational cost to implement outbreak control measures, false-positive results may also lead to overestimating COVID-19 true incidence and the overall burden of the disease. Recently in Saskatchewan, Canada, 255 COVID-19 test results were deemed to be invalid after a testing error was identified at a provincial laboratory. After retesting, 206 results were found to be false positive [17]. Prior to this verification, outbreaks or suspected outbreaks were already declared in several long-term care homes across the region. Also, my team conducted a survey in Ontario, Canada from August 2020 to March 2021, and found that out of 64 suspect or confirmed COVID-19 outbreaks in some long-term care homes, 23 (36%) were deemed to be pseudo-outbreaks (no clinical or epidemiological correlation) with discordant results that were subsequently determined to be false positive (negative). In most of the cases, outbreaks were declared and then called off when further testing of specimens gave negative results (false positive). In other situations, local health units treated the events as true outbreaks even though the results of repeat testing were negative or discordant. These data and those from other sources suggest how errors in laboratory tests or other types of tests. Public health authorities must strengthen their diagnostic algorithms in order to guide outbreak declarations and downstream public health interventions.

From an epidemiological standpoint, one of the key steps in outbreak response is verifying the diagnosis, or establishing the existence of an outbreak [18]. Verifying the diagnosis is important to:

(a) ensure that the causative agent has been properly identified, since control measures are often disease-specific;
(b) rule out the possibility of laboratory errors or pseudo-outbreaks; and,
(c) to interpret laboratory findings in line with the clinical and epidemiologic findings [18].

Currently, most surveillance systems exclude persons who have been recently infected with COVID-19 (i.e., within 90 days) from routine surveillance testing. Therefore, persons who were deemed as positive when probably they were not (false positive) are excluded from the surveillance testing and this could create an opportunity of risks as these persons could indeed become infected and spread the virus as they are not included in routine asymptomatic surveillance testing [19].

Together, prior to outbreak declaration, diagnostic verification has often not been fully investigated and facilities have been plunged into outbreak status without a thorough investigation or due diligence on the part of some health units. The need to apply the precautionary principle during uncertainty is understood, but this should not obviate the requirement to definitively establish the existence of an outbreak using epidemiologic, clinical and scientific principles. In fact, declaring a COVID-19 outbreak should not be made solely on the basis of a single positive PCR result, even involving more than two cases, but should include an assessment of signs or symptoms, epidemiologic links and then confirmed by additional PCR tests or other types of tests. Public health authorities must strengthen their diagnostic algorithms in order to guide outbreak declarations and downstream public health interventions.

POSITION STATEMENT: Infection prevention and control program components for long-term care homes

This position statement was developed by IPAC Canada Long Term Care Interest Group.
Chair: Cathy Guitare/Anne Augustin
Principal Authors: Anne Augustin and Clare Barry

Original Publication Date: July 2021

Disclaimer: This document was developed by IPAC Canada based on best available evidence at the time of publication and is meant to provide advice to Infection Prevention and Control Professionals. The application and use of this document are the responsibility of the user. IPAC Canada assumes no liability resulting from any such application or use.

BACKGROUND
Residents of long-term care homes (LTCHs) are a vulnerable population. As a result, there have been many outbreaks with significant morbidity and mortality caused by a plethora of different micro-organisms (influenza A, SARS-CoV-2, Group A Streptococcus, methicillin-resistant Staphylococcus aureus [MRSA], Carbapenemase-producing Enterobacteriaceae [CPE], norovirus, Clostridioides difficile, extended spectrum beta-lactamase-producing organisms [ESBL], hepatitis B and C) amongst others [1-5]. There are currently no national IPAC recommendations specifically for an IPAC program in LTCHs, although there have been publications recommending IPAC programs and resources [6-10]. LTC and retirement homes have been disproportionately affected by COVID-19 in Canada with 10% of all Canadian COVID-19 cases (about 80,000), resulting in more than 66% of the national deaths (over 14,000 deaths in residents and close to 30 staff) as of February 2021. More than 2,500 homes experienced an outbreak, and the proportion of COVID-19 deaths in Canadian LTC and retirement home residents (69%) exceeds the international average (41%)* [5]. As per federal and provincial/territorial legislation, employers shall ensure that the LTC setting is a safe work environment which protects residents and staff [6].

POSITION STATEMENT
The goals of an IPAC program are to protect residents from healthcare-associated infections and to prevent the spread of infections among residents, healthcare providers, staff, visitors, and others in the healthcare environment [6]. Active, evidence-based IPAC programs that are continuously supported by senior leadership and evaluated on a yearly basis have been demonstrated to decrease the morbidity, mortality and financial burden of outbreaks in LTCH [1,2,6,7]. The IPAC program should include, as a minimum, the following elements:

Human Resources
• One dedicated full-time equivalent (FTE) Infection Prevention and Control Professional (ICP) per 150-200 occupied beds [6-10].
  o Where an increase in acuity and complexity of resident care exists (e.g., chronic ventilation, dialysis, and specialized programs for spinal cord injuries, psychiatry and cognitive impairment), one FTE ICP per 150 occupied beds is recommended [7,8].
  o For homes with fewer than 150 beds, where possible, a dedicated FTE ICP is preferred, especially if combined with a related role (e.g., clinical education). The ICP staffing level should be sufficient to ensure that all the components of the IPAC programs are met as outlined in this position statement.

New ICPs are enrolled in an IPAC-Canada-endorsed training program, which includes the core competencies as described in the document IPAC Canada Core Competencies for Infection Control Professionals [11]. Training should commence within the first six months of entering the profession. New ICPs are ideally mentored by an experienced, CIC® certified ICP after hire [7,8]. IPAC Canada endorses certification in Infection Prevention and Control through the Certification Board of Infection Control (CBIC) [12].
• The expected number of hours per week that are devoted to infection prevention and control must be clearly stated and protected [8].
• Access to a physician with the expertise of IPAC [7,8] whose professional development in IPAC includes:

This position statement was developed by IPAC Canada Long‐Term Care Interest Group.
Chair: Cathy Guitare/Anne Augustin
Principal Authors: Anne Augustin and Clare Barry

Original Publication Date: July 2021

Disclaimer: This document was developed by IPAC Canada based on best available evidence at the time of publication and is meant to provide advice to Infection Prevention and Control Professionals. The application and use of this document are the responsibility of the user. IPAC Canada assumes no liability resulting from any such application or use.
The LTCH ICP should be a member of IPAC Canada and IPAC education is also to be provided to residents, families, and healthy workplace policy. 

Education/training is to include as a minimum: hand hygiene, point-of-care/personal risk assessment, routine practices, additional precautions, correct donning and doffing of personal protective equipment (PPE), healthy workplace policy, safe management of sharps, immunization, work restrictions due to infectious diseases, equipment cleaning and disinfection, and environmental cleaning [6-9,19].

**Laboratory**

LTCHs should have a collaborative relationship with a licensed and accredited microbiology laboratory. There should be a system to alert the IPAC program when targeted microorganisms are isolated or detected and provide laboratory reports in a timely manner [7,8,10].

**IPAC Policies/Procedures**

Policies and procedures should be developed from current, evidence-based federal, provincial, territorial and Accreditation Canada guidance/recommendations and legislation, and include as a minimum:

- A hand hygiene program, which includes hand skin care, reflecting the IPAC Canada Practice Recommendation on Hand Hygiene [8,13-16].
- Point-of-Care Risk Assessment, Routine Practices and Additional Precautions [6,8,16-18].
- Outbreak management [6,10,19,20]. In the event of a pandemic, LTCHs will abide by the provincial and federal directives.
- Cleaning of the environment shall be as per national and provincial/territorial guidance [6-8,21].
- Cleaning and disinfection of reusable and shared medical equipment shall be as per national and provincial/territorial guidance [6-8,17,18,21-23].

**Education and Training**

- All healthcare providers (HCPs) and other staff, including contract staff, are to have IPAC training upon hire, on a regular basis, at least annually, and as needed (e.g., based on audit results, during an outbreak or identification of significant organism, or as directed by provincial/territorial legislation) [6-10,20].
- Education/training is to include as a minimum: hand hygiene, point-of-care/personal risk assessment, routine practices, additional precautions, correct donning and doffing of personal protective equipment (PPE), healthy workplace policy, safe management of sharps, immunization, work restrictions due to infectious diseases, equipment cleaning and disinfection, and environmental cleaning [6-9,19].
- IPAC education is also to be provided to residents, families, visitors, sitters/companions and volunteers as indicated, and includes hand-hygiene, Capitals on Routine Practices and Additional Precautions, correct donning and doffing of PPE, and healthy workplace policy [7-9,19].
- The LTCH ICP should be a member of IPAC Canada and their local chapter to support ongoing education and networking [10].

**Occupational Health Program**

- IPAC collaborates with this program, which includes, at a minimum, a healthy workplace policy, a sharps safety program, review of immunizations, TB screening, a hand skin care program, and a process for monitoring trends for any communicable infections, such as acute respiratory infection and gastroenteritis, in HCPs and other staff [7,8,18-20].
- A Resident Immunization Program (e.g., influenza, pneumococcal vaccine, pandemic vaccines), which follows the National Advisory Committee on Immunization (NACI) recommendations [7,20,24].

**Surveillance Program**

Process and outcome surveillance is required to ensure data is systematically collected, collated, analyzed, and disseminated to those who require it to take action [6,25]. The surveillance program has a written process, which is evidence-based and is aligned with provincial/territorial legislation requirements for surveillance and reporting, and takes into account local epidemiology [6-8,25-28]. As a minimum surveillance shall include:

- Admission screening, active syndromic surveillance (e.g., respiratory infection and gastroenteritis), and identification of sentinel events (e.g., invasive group A Streptococcus, SARS-CoV-2);
- Process audits (e.g., compliance with Routine Practices and Additional Precautions, including hand hygiene, PPE use, environmental cleaning, shared equipment cleaning);
- Antimicrobial stewardship (e.g., asymptomatic bacteriuria/urinary tract infections, Clostridioides difficile)

**Facility Design, Renovation and Maintenance**

The ICP is included as part of the multidisciplinary team/project team. The ICP has an important role in the prevention of infections throughout any construction/renovation/maintenance or facility design project [29-34]. For any renovations or redevelopment, the Canadian Standards Association’s (CSA) document, Z8000 Canadian healthcare facilities, should be followed with respect to design with the goal to eliminate multi-bed rooms (i.e., ensuring single rooms with a single resident dedicated bathroom and sink). Studies have shown a clear relationship between use of single rooms and the reduction in infection transmission [18,29,32-34]. The CSA Z317-13 document, Infection control during construction, renovation, and maintenance of healthcare facilities, should be followed for IPAC measures needed during construction/renovation/maintenance of a facility [29,31].

**GLOSSARY/DEFINITIONS**

As per the Canadian Standard Association (CSA):

“SHALL” is used to express a requirement, i.e., a provision that the user is obliged to satisfy in order to comply with the standard.

“SHOULD” is used to express a recommendation, or that which is advised but not required; and

“MAY” is used to express an option, or that which is permissible within the limits of the standard, an advisory or optional statement.
Healthcare provider: Any person delivering care to a client/patient/resident. This includes, but is not limited to, the following: emergency service workers, physicians, dentists, nurses, respiratory therapists and other health professionals, personal support workers, clinical instructors, students and home healthcare workers. In some non-acute settings, volunteers might provide care and would be included as a healthcare provider. See also, Staff [7].

Long-term care home: A long-term care home (LTCH) provides care and services for people who are no longer able to live independently, or who require onsite nursing care, 24-hour supervision, or personal support.

Staff: Anyone conducting activities in settings where healthcare is provided, including healthcare providers. See also, Healthcare providers [7].

Stakeholders: LTCH management and healthcare providers, residents, families and visitors and the community at large.

ABSTRACT
Background: The COVID-19 pandemic was a challenge for all dental professionals who had to rapidly update infection prevention and control (IPAC) guidelines and protocols due to increased risk of SARS-CoV-2 transmission during common aerosol-generating procedures (AGPs), and a lack of consensus on how best to mitigate the risk of transmission in a dental office. Thus, the purpose of this descriptive study was to compare the variance in IPAC guidelines for dental offices that emerged, and to assess practice consistency from early to mid-2020.

Methods: A comprehensive literature search was conducted from May 26 to July 8, 2020 for IPAC documentation specific to the dental office during the COVID-19 pandemic. Documents that met the inclusion criteria were independently reviewed. Data was extracted using a framework based on the following IPAC domains: pre-appointment, waiting room, personal protective equipment (PPE) selection, treatment room, and post-dismissal.

Results: A total of 67 IPAC documents specific to dental offices were reviewed in this study. Included documents originated from 22 dental associations, 17 peer-reviewed articles, 13 dental regulators, 11 government bodies, two public health units, and two dental corporations. There was a great degree of variance with IPAC guidelines from the pre-appointment stage, during treatment, and post-treatment. Recommendations that emerged with some level of consistency involved pre-screening patients for COVID-19 symptoms (97%), staggering appointments (84%), social distancing, minimizing occupants in the waiting room, wearing a face shield over protective eyewear for AGPs (92%), and preprocedural rinses (84%). There was less consistency with recommendations for consolidating multiple appointments (36%), waiting room ventilation (46%), N95 masks (47%) versus FFP2/FFP3 masks (30%) use for AGPs, fit-testing respirators (37%), enclosing open operatories for AGPs (28%), prioritizing minimally invasive procedures (30%), and using third-party laundry companies (32%).

Conclusions: The risk of SARS-CoV-2 transmission, lack of consensus on mode of spread, and need for rapid action resulted in a significant variation in most downstream IPAC interventions in the hierarchy of controls, including choice of PPE, treatment room, and post-dismissal domains. Upstream interventions, including pre-appointment and waiting room domains, were relatively consistent in practices in early to mid-2020.

KEYWORDS: aerosols, COVID-19, dentistry, guideline, infection control

INTRODUCTION
The coronavirus disease (COVID-19) was first identified in Wuhan, China in December, 2019 after a group of patients presented to the hospital with atypical pneumonia [1]. Evolving transmission patterns of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and elusive variants have challenged public health strategies and prolonged the pandemic [2]. SARS-CoV-2 can be transmitted by direct contact with contaminated surfaces, contact with discharge from nose or mouth, and most commonly via droplet dispersion when an infected person coughs, sneezes, or undergoes an aerosol-generating procedure (AGP) [3]. Most dental procedures generate aerosols that are contaminated with a patient’s saliva, blood, secretions, or tissue particles [4]. Due to increased transmission risks during dental AGPs, dental treatment in most countries across the world was paused and limited to emergency care in the early stages of the pandemic [3]. Dental clinics gradually re-opened in phases under strict infection prevention and control (IPAC) guidelines mandated by public health authorities and dental regulators. Each authority responsible for creating guidelines had to review new information as it became available and update their guidelines.

Considering the proximity of dental care providers (DCPs) to patients during treatment and the contamination and spread of aerosols, dental offices were considered to be a high-risk setting for COVID-19 transmission [5]. The disease can readily...
spread from infected patients to the DCPs, to other patients and vice versa without appropriate IPAC protocols. Longstanding measures include personal protective equipment (PPE), hand hygiene, proper equipment handling and sterilization, procedural risk reduction, and disinfection and sterilization protocols [6]. Considering the risk of transmission of COVID-19 in dental settings, dental professionals had to re-evaluate the entire dental continuum of care, including tracking patients through the entire array of dental services from pre-appointment, waiting room, PPE selection, treatment room, and post-dismissal. Guidelines demanded that offices were redesigned to accommodate social distancing, minimize contact points, and conform with overarching public health mandates.

Since it is imperative that dental offices adapt strategies to mitigate the spread of COVID-19 aerosols, in this study, we reviewed interventions for consistency. In the dental setting, droplets from AGPs can reach the DCP’s eyes and nose, which could increase the likelihood of SARS-CoV-2 transmission [7,8]. Particulate respirators filter out 0.1 to 0.3 micron particles during AGPs [9]. Protective eyewear and face shields may prevent infectious droplets from contaminating conjunctival epithelium [10]. Hydrogen peroxide (HP), chlorhexidine (CHX), and povidone iodine (PI) preprocedural rinses (PPRs) may reduce viral loads of SARS-CoV-2 in saliva and oropharyngeal tissues, and consequently in aerosols [11–13]. Aerosol transmission can be mitigated at the source via rubber dam isolation, high-volume evacuation and allowing a “fallow time” for air circulation and droplet settling [14].

As information on the transmission and epidemiology of COVID-19 continues to evolve, policymakers interpret scarce scientific evidence and changing advice from international health agencies to develop guidelines for safe delivery of oral healthcare services. A rapidly evolving understanding of the infectiousness and transmissibility of COVID-19, scarce evidence supporting novel IPAC measures in dental offices, and unique risk of acquiring COVID-19 via aerosol created the “perfect storm” for inconsistent recommendations. Thus, the aim of this study was to identify variance in IPAC guidelines specific to dental offices in early to mid-2020 of the COVID-19 pandemic, from pre-appointment, waiting room, PPE selection, treatment room, and post-dismissal.

METHODS
A comprehensive search for IPAC documents specific to dental offices during the COVID-19 pandemic was conducted by an independent reviewer (DW) between May 26, 2020, and July 8, 2020. Both authors (KD and DW) independently reviewed documents to create a mutually agreed upon inclusion list. Inclusion criteria included English language guidance documents by professional bodies for dentists, guidance from national or subnational (i.e., province or state) bodies, peer-reviewed scientific publications, guidance for resuming or maintaining dental practice during the COVID-19 pandemic, guidance for the entire continuum of dental care from pre-appointment, waiting room, treatment room, and post-dismissal. Consensus statements, guidance for dental auxiliaries, local (i.e., town, city, or county) guidance and sources exclusively focusing on select recommendations, or not specific to dentistry were excluded.

A search for IPAC documents and publications was conducted using the following databases: MEDLINE, EMBASE, Scopus, Cochrane Library, and Google Scholar. The following terms and Boolean operators were used in MeSH and free-text searches: OR infection OR prevention and OR control, OR emergency, OR urgent, OR non-urgent, AND dental OR settings, OR oral OR health OR services, OR IPAC, OR interim, OR phase 1, OR phase 2, OR phase 3, OR plan, OR procedure, OR guidance, OR guideline, OR return, OR recovery, OR practice, OR dentistry, OR covid-19, and OR return to work. Additionally, a search of the grey literature was conducted to identify IPAC documents produced directly by dental associations, regulatory bodies, and governing health authorities.

Eligible IPAC documents were reviewed and the following document elements were first extracted: country/region of publisher, organization name, type of organization (i.e., health authority, dental association, dental regulator), document title, publisher, organization name, type of organization (i.e., health authority, dental association, dental regulator), date of publication, and whether or not it was a live document (Supplementary Table 1). A framework for extracting IPAC content was developed in advance based on the following stages of patient flow through an office: pre-appointment, waiting room, treatment room, and post-dismissal. The collected data was organized according to theme, and descriptive data is reported. The proportion (%) of each individual recommendation category was calculated by relating frequency to total number of guidelines.

RESULTS
Recommendations were summarized according to frequency of recommendation variations and proportion of sources represented for patient flow categories. The initial search identified 127 documents; 100 documents were fully reviewed, and 67 guidance documents were selected after exclusions. The full review of search process is described in Figure 1.

Pre-Appointment
A summary of pre-appointment recommendations is presented in Table 1. Almost all (97%) guidelines recommended pre-screening patients and temporally scheduling according to COVID-19 risk. Interestingly, only 10% of the guidelines reviewed recommended implementing a COVID-19 staff informed consent form prior to returning to work after the initial COVID-19 shutdown. The purpose of the form was to make staff aware of the risks involved upon returning and working during the COVID-19 pandemic. The majority (81%) of guidelines recommended staggering appointments to minimize patient-to-patient contact and 36% recommended combining appointments when possible.

Waiting Room
A description of recommendations specific to dental office waiting rooms is presented in Table 2. Most guidelines (88%) adopted local public health recommendations for the waiting room such as social distancing, hand hygiene, and minimizing contact points. A total of 83% of sources recommended
installation of a clear plastic barrier at the reception desk. Ninety-two percent of sources recommended minimizing occupants to allow for social distancing – most of these sources recommended social distancing of at least two metre (72%), while others recommended one metre (22%). Less than half (46%) of the guidelines recommended improving airflow in the waiting room, either by opening windows or using air-filtration systems. Almost all guidelines promoted passive screening, including requirements for patient hygiene (92%), and placement of COVID-19 information posters (81%).

### Personal Protective Equipment
A summary of relevant PPE recommendations is presented in Table 3. PPE recommendations were stratified based on COVID-19 infection status of patients and type of procedure (AGP or non-AGP). Only 62% of sources recommended wearing an additional face shield over protective eyewear for non-AGPs on unsuspected COVID-19 patients. Conversely, for AGPs, the large majority (92%) of sources recommended wearing a face shield over protective eyewear for all patients. Very few (3%) sources considered an American Society for Testing and Materials
(ASTM) level 3 mask and face shield as an alternative to a 95% filtration efficiency respirator (N95) or filtering facepiece class 2 or 3 (FFP2/FFP3) for AGPs. Only 37% of sources required that respirators are fit-tested prior to use. Over half (51%) of sources recommended wearing an N95 respirator and only a third (33%) of the guidelines recommended wearing an FFP2 or FFP3 respirator for AGPs on suspected COVID-19 patients. More than three-quarters (76%) of sources recommended wearing a protective gown for bodily protection during all procedures.

### Treatment room

IPAC recommendations for treatment rooms and during procedures are presented in Table 4. Select sources (28%) mandated separation of operatories with plastic barriers (from floor-to-ceiling) for AGPs for suspected or confirmed patients with COVID-19. Very limited sources (16%) required AGPs on COVID-19 patients to be completed in airborne infection isolations rooms (AIIRs). Sixty-one percent of sources addressed fallow time after AGPs. Of these sources, about half recommended (49%) a fallow time of less than 60 minutes, some (20%) recommended a fallow time of 1–3 hours, and others (22%) specifically stated that a fallow time was not required. There was widespread (84%) agreement for PPRs, most commonly (63%) recommending an HP rinse, followed by PI (45%). About two thirds (66%) of sources recommended practicing with an assistant at all times for constant use of high-volume suction, often denoted as “four-handed dentistry”. Most (93%) guidelines emphasized the importance of utilizing a rubber dam and other isolation techniques such as PVS-based isolation pastes, cotton rolls and gauze, and cheek retraction suction devices. Only 30% of sources recommended prioritizing minimally invasive operative procedures such as chemo-mechanical caries removal, Hall technique, atrumatic restorative technique (ART), or silver diamine fluoride. Very few (7.5%) sources recommended avoiding prescription of ibuprofen due to potential aggravation of COVID-19 infection.

### Post-Dismissal

A summary of post-dismissal recommendations of interest is listed in Table 5. About one-third (32%) of sources recommended daily collection of reusable gowns and scrubs by a third-party laundering service. About half (49%) of
sources recommended that staff wear standard PPE during disinfection/decontamination procedures, including eyewear, gloves, and mask. Of sources that recommend alcohol-based surface disinfection products (25%), a 62-71% alcohol-based surface solution was most frequently recommended (41%). Some guidelines (22%) asked that patients inform the clinic if they develop symptoms, or are diagnosed with COVID-19 after treatment for contact tracing and isolation of close contacts. Of these, 53% required follow-up after two days, and 33% for 14 days.

Discussion

This study compares and contrasts the different IPAC guidelines that emerged specific for dental offices during the COVID-19 pandemic for pre-appointment, waiting room, PPE use, treatment room, and post-dismissal domains. Among 67 guidelines included, various recommendations were homogeneous in each category. This includes pre-appointment recommendations such as pre-screening and staggering appointments and waiting room recommendations such as social distanced seating, hand hygiene, and COVID-19 information posters. Most pre-appointment and waiting room recommendations were not specific to the dental environment and matched overarching public health guidelines that were relatively consistent internationally. There was agreement in PPE choice, treatment room, and post-dismissal measures supported by evidence available at the onset of the pandemic. Both cost-effective and reusable, face shields were uniformly recommended for AGPs. Face shields have been shown to reduce immediate viral exposure by 68-96% during AGPs [15]. Wearing a disposable or reusable protective gown was also widely recommended, and shown to be effective in reducing infection rate [16,17]. Treatment room guidelines were most alike in recommending a fallow time of less than 60 minutes, which preliminary evidence supports, including the use of PPRs [18,19]. Similarities existed in post-dismissal recommendations for the use of 62-71% ethanol disinfectant, that has been shown to rapidly inactivate human coronaviruses in experimental studies, and intuitive use of eye protection, gloves, and mask during disinfection [13].

Widespread agreement in recommending PPRs can be accounted for by the pre-existing body of literature available demonstrating their effectiveness in significantly reducing microbes in dental aerosols [20]. Three of the most recommended rinses include HP, PI, and CHX. However, the majority of studies referenced evaluated microbial loads using colony-forming units, which excludes viruses [11,21–25]. Hypothetical inferences were made from the available research demonstrating that these PPRs reduced aerosol loads of other enveloped viruses in different capacities, depending on concentration and duration of use [20,26]. More recently, PI was shown to completely deactivate SARS-CoV-2 after 15 seconds in-vitro and reduced salivary viral load up to six hours after use in COVID-19 positive patients [27,28]. PI may not be most commonly recommended because of infrequent adverse events reported such as burning sensation, itching, and local irritation [29]. CHX was least frequently recommended for AGPs. Face shields have been shown to reduce immediate viral exposure by 68-96% during AGPs [15]. However, the majority of sources adopted a social distance measure of two metres, there were still some recommendations for a shorter distance of one metre, which is likely explained by local differences in public health orders. Evidence suggests SARS-CoV-2 may travel more than 2m through coughing and shouting [31]. Stark differences in PPE recommendations were noted for respiratory hygiene; N95 respirators during AGPs versus FFP2/FFP3 respirators despite similar filtration efficiency [9]. This can be explained by geographic standardization of N95s in North America and FFP2/FFP3s in Europe [9]. Only few advocated for fit-testing respirators as this may have been included in general healthcare service guidelines that encompassed DCPs, as it has been established that fit-testing increases protective factors offered by respirators [32].

Lack of consensus surrounding aerosol transmission of COVID-19 and limited research on dental AGPs resulted in significant variance in suggestions for air control in operatories. Fallow time also depends on each unique facility’s air circulation variables, complicating recommendations [14]. Only 22% of guidelines stated that a fallow time was not required after AGPs. The effectiveness of fallow time may have been overstated early in the pandemic. A recent study suggested that intraoral high-volume suction alone or in combination with other air-cleaning methods reduced particle concentrations to baseline on completion of AGPs and may negate need for fallow time [4]. Those responsible for drafting guidelines likely looked to professional agencies like the CDC and/or WHO for early IPAC guidance because of insufficient experimental evidence about COVID-19. CDC guidelines recommended that practices determine fallow times using NIOSH’s mathematical relationship for rate of decline in concentration of airborne contaminant [33]. This hypothetical model assumes the aerosolized environment is an empty room with ideal mixing of room air after the contaminant source is removed [14].

Minimally invasive restorative procedures, which would not generate aerosols, were not frequently endorsed. However, most guidelines did recommend avoiding AGPs when possible. Beyond the benefit of conserving tooth structure, clinicians may opt for evidence-based, minimally invasive procedures more frequently for the management of caries because they reduce or eliminate aerosol transmission [34]. Only five sources recommended avoiding the prescription of ibuprofen after a letter published in the Lancet on March 11, 2020 hypothesized that ibuprofen may aggravate COVID-19 symptoms [35]. Shortly after, a retrospective cohort study by Rinott et al. showed that ibuprofen was not associated with worse clinical outcomes [36]. Most sources did not recommend professional out-of-house laundering potentially due to controversy in the literature on whether soiled linen risks disease transmission. The CDC stated that it presents a negligible risk for infection and
normal ‘hot’ and ‘cold’ washing-drying cycles are adequate for patient safety.” While the Association of Surgical Technologists recommended professional laundering due to the extent of contamination [37]. This is an opportunity for practice leaders to review dress code policies to ensure safety for patients and providers. Introducing research opportunities for how different aspects of scrubs may impact contamination (i.e., material and duration of use). The dichotomous difference in contact tracing recommendations between two and 14 days can be explained by national differences in public health protocols post-confirmation and ambiguity in the virus’ infectious period [38].

The potential airborne nature of COVID-19 and ability to rapidly disseminate demanded that decision-makers revamp protocols to include overriding public health measures. Simultaneously, guideline creators had to address dental-specific concerns of COVID-19, namely AGPs. The need to define dental AGPs in guidelines created ambiguity, however, the use of high-speed handpieces, air-water syringes, and ultrasonic scalers were consistently considered AGPs [39]. Virdi et al. found that risk stratification of COVID-19 transmission associated with different AGPs was inconsistent among early guidelines, but guidelines released later were more descriptive [39]. During initial reopening, it may have been rational to expect inconsistent guidelines for a novel viral pathogen; evidence consulted was likely based on rapid reviews and mixed findings from published data. To fill this gap, current research has focused on many of these uncertainties resulting in rapid production of a large volume of literature [40]. Bibliometric analysis by Jacimovic et al. analyzing 296 dental COVID-19 studies identified a low overall level of scientific evidence [40]. The authors concluded that current literature does not provide sufficient data for the evidence-based decision-making process required for guiding clinical practice [40]. It will be important to thoroughly analyze the vast COVID-19 scientific evidence available to corroborate new findings specific to dentistry.

Robust IPAC protocols existed in dentistry prior to the pandemic but the uncertainty with regards to infectivity and transmissibility of the virus challenged norms. Importance placed on IPAC in dental settings can be appreciated by the lack of super-spreader events involving dental practices in the literature [33]. Following the precautionary principle, in the absence of definitive scientific evidence on how to prevent transmission in a dental office, policymakers and dental regulators had to err on the side of caution to protect the public. The level of caution dental authorities took to account for growing uncertainty and complexity reflects itself in the variety of different guidelines observed. Current guidelines have not changed significantly, but have only become more lenient. Identifying variations in guidelines emphasizes where certain recommendations may have been understated if they were only captured in multidisciplinary or broad public health orders that offices adhered to. There have been considerable developments since initial search in early to mid-2020, such as ventilation and engineering controls, vaccinations, and variants of concern that are not reflected in this study.

CONCLUSION

Due to the transmissibility of the SARS-CoV-2 virus, limited evidence, and short time period to act, our study demonstrates a considerable variation in downstream IPAC recommendations specific to dental offices in the domains related to PPE choice, treatment room, and post-dismissal recommendations. Upstream interventions that focused on eliminating exposure through pre-appointments and precautions in the waiting room were fairly consistent across guidelines. While pre-COVID-19 IPAC guidelines for dental offices were once considered robust, this pandemic revealed areas that need to be addressed in the post-pandemic world. Moving forward, a greater emphasis needs to be placed on developing evidence-based IPAC guidelines that will allow dental professionals to provide safe and effective treatment.

**ABSTRACT**

Healthcare workers are at high risk of contracting infections including COVID-19 due to close and frequent contact with patients. To promote appropriate use of personal protective equipment (PPE) and to enhance protection of healthcare workers during the COVID-19 pandemic, we trained a team of registered nurses to serve as “PPE Spotters”. This team offered in-person observation, support, feedback, and on-the-spot teaching about proper PPE use and hand hygiene practices. Evaluation showed staff and leaders felt the Spotters effectively promoted best practices for PPE and hand hygiene, and 86% recommended the program continue. PPE Spotters now serve a formal role in the organization, supporting both acute and long-term care.

**KEYWORDS:** PPE, pandemic, COVID-19, infection control, PPE spotter

**BACKGROUND**

Healthcare workers are at high risk of contracting infections because of close and prolonged contact with patients. Staff-to-staff transmission of infections, including COVID-19 has also been reported, with crowded staff breakrooms (where staff must remove their masks to eat), presenting the greatest concern [1], while inconsistent PPE use by staff during breaks provides another potential source of transmission [2]. High-touch surfaces and poor ventilation inside breakrooms may also contribute to transmission of infections among staff [3, 4]. Consequently, proper use of PPE, good respiratory etiquette and impeccable hand hygiene are integral to preventing the spread of infectious organisms. Since the start of the COVID-19 pandemic, many healthcare organizations have developed innovative approaches to assist staff with appropriate use of PPE while conserving PPE supplies, and supported the ongoing practice of excellent hand hygiene. In some healthcare organizations, the role of the infection prevention and control (IPAC) team is extended to appropriate PPE use teaching, monitoring, and coaching. In the past year, published literature has offered examples of new supporting roles, such as PPE Spotters: personnel who assist staff with proper donning and doffing of PPE and reduce the misuse of PPE [5, 6].

PPE Spotters in a Chicago hospital educated staff on the types of PPE equipment needed for various tasks, and it was shown that the misuse of N95 respirators (specific for filtering airborne particles) decreased following implementation of the Spotter role [6]. A Pennsylvania hospital noted that their “PPE Subject Matter Experts” effectively provided shoulder-to-shoulder support, which resulted in delivery of optimal PPE training to care providers during the pandemic [5]. The role of the PPE Spotter is also significant in ensuring effective communication among care staff and leadership teams, including IPAC, during uncertain times [5]. Frost et al. further suggest that PPE “donning and doffing is best performed under close observation by a PPE Spotter” who is empowered to intervene if there is a breach in PPE, thus allowing for “focused attention” on the importance of proper PPE use [7]. In April 2020, our IPAC team created a “PPE Spotter” role and trained registered nurses (RNs) for this position. A formal evaluation of this role was conducted four months later. At present, there are no other known published studies on the evaluation of the PPE Spotter role during the COVID-19 pandemic.

**METHODS**

Our organization includes acute care hospitals, long-term care centres, and community clinics. In addition to the PPE Spotter program, our organization created “Screeners” who were positioned at each site’s public entrances to administer health questionnaires and monitor PPE use by those entering the facility.

Conflicts of Interest: The authors declare that they have no conflict of interest.

Acknowledgements: We are grateful for the support of Camille Ciarniello, the original PPE Spotters, Ali RajabiMemar and Eleanor Marsh, as well as the other nurses who have filled the PPE Spotter role.
Twenty RNs were trained as PPE Spotters, some of whom filled the role temporarily. PPE education sessions reached close to 1,600 staff across the organization. RNs from disciplines including IPAC and surgical services (available due to temporary shut-down of surgeries), as well as members of the Professional Practice Office were trained as PPE Spotters. Training was conducted by staff from IPAC and the Professional Practice Office, and included a refresher course in IPAC guidance around infection control (including COVID-19) and PPE use, as well as tips on using a coaching approach when offering staff support with PPE use and hand hygiene. PPE Spotters primarily worked day shifts, and initially visited units across acute care to offer support in best practice related to the use of PPE and infection control principles. The Spotters watched for opportunities to assist staff with using PPE, offering in-person observation, feedback and on-the-spot teaching about proper PPE use and hand hygiene.

The Spotters also led PPE education sessions, offered to all staff who provided direct care and those in non-clinical roles including security, food-service staff, and patient transfer personnel. Spotters created and distributed laminated posters to demonstrate proper donning and doffing of masks, gowns, and gloves, as well as signage to denote PPE required in patients’ rooms and other care areas. In some medical units, Spotters also led decluttering efforts to facilitate thorough cleaning of the area.

Four months after introducing the PPE Spotters in acute care areas, the program was evaluated in an organization-wide survey offered to all staff, using distribution lists that included approximately 3,000 staff. Survey questions included demographics, Likert-scale perceptions, and an open-ended question to solicit suggestions for improving the program. The survey was advertised in organizational newsletters, and a gift card draw was created to encourage responses. In total, 221 responses were received from a diverse set of staff and clinicians. Results were compiled and shared in the organization’s newsletter.

RESULTS
Survey results showed strong support for the PPE Spotter program, with 86% (173/202) of respondents recommending the program continue. Seventy-four percent (163/219) of respondents were aware of the Spotter program and 53% (112/213) reported having had interactions with a PPE Spotter. Overall, 61% (124/203) of respondents agreed that the PPE Spotter program was helpful in supporting best practice for PPE and hand hygiene on the units. Feedback from staff indicated they appreciated PPE Spotters for being “patient yet clear with their approach to correcting PPE practices,” and also greatly appreciated clarity about donning PPE for specific indications, especially pertaining to airborne precautions. Additionally, the Spotters “in-the-moment feedback” was stated to be more valuable than “audits shared later”. Respondents also emphasized their appreciation for PPE educators and advocated that this resource “be [offered] in every hospital area”. Sixty-one percent (125/204) of respondents agreed that PPE Spotter support was helpful in reducing the potential spread of COVID-19. One senior leader noted, “I believe the support of the Spotters has been instrumental…I believe that when we support each other to don and doff safely, we save lives. Thank you!” (Sandra Barr, MHA, email communication, June 3, 2020). The survey also generated many suggestions to expand and improve the PPE Spotter program, including offering PPE Spotters in long-term care sites, adding evening and weekend shifts, and emphasizing a supportive approach in all interactions.

In August 2020, the PPE Spotter program was expanded to all long-term care sites and the PPE Spotter role has since been formalized with dedicated staff.

DISCUSSION AND CONCLUSION
As the COVID-19 pandemic enters its second year, and with several new variants reported in recent months, healthcare organizations face the prospect of ongoing need for PPE and hand hygiene support for healthcare workers. The nature of the COVID-19 pandemic and associated outbreaks of disease make it difficult to attribute the support offered by roles like the PPE Spotter to a reduction in the number of COVID-19 outbreaks or the duration of these outbreaks. Other new practices adopted since the pandemic, such as the Screeners, may affect this outcome. However, staff and leaders believe that the support and education offered by the PPE Spotters contributed to reducing the transmission of COVID-19 and number of outbreaks across facilities. Additionally, the expansion of the Spotter program to long-term care sites, where the workforce consists of primarily supportive roles such as care aides who may have less experience of PPE use, has received overwhelming support by site leaders. This evaluation is limited by the low number of responses received, relative to the number of staff employed at our organization. We believe the additional strain placed on staff by working during the pandemic reduced the number who were able to respond to the survey. Future evaluations of the PPE Spotter program could assess staff perceptions of practice change related to PPE Spotter support as well as the effectiveness of the program in long-term care sites. The implementation of a PPE Spotter program is a promising practice for infection prevention and control in both acute and long-term care settings, especially given the Spotter role requires little additional training for practicing RNs and has been well received by staff and leaders.

KEYWORDS: Clinical reasoning, clinical trials, evidence-based medicine, SARS-CoV-2, treatment

The COVID-19 pandemic represents one of the largest acute global health threats in a century, and scientific and public interest in the disease is substantial. Clinicians, infection control practitioners, epidemiologists, policymakers, and concerned citizens worldwide are looking to medical journals, preprint servers, and social media for updates on the prevention and treatment of this disease.

As scientists and clinicians scramble to understand this new infection, there has been a deluge of scientific publications about the epidemiology, pathophysiology, diagnosis, and treatment of COVID-19. There have been some remarkable milestones in phase 3 clinical trials going through design, ethics approval, enrolment, analysis, and publication within the past six months. The first is the randomized controlled trial by Cao et al on the use of lopinavir-ritonavir for severe COVID-19 [1]. The trial began enrolment on January 18, 2020, only weeks after the discovery of SARS-CoV-2, and was published only two months after enrolment. The same group successfully completed a 2:1 randomized controlled trial on remdesivir versus placebo, and although recruitment was hindered by the end of the local outbreak, it still contributed useful findings [2]. The first robust randomized controlled trial to be published on COVID-19 involved the recruitment of over 1,000 individuals from 10 countries to receive remdesivir or placebo, a remarkable achievement in the context of a pandemic with a short time frame [3]. These trials have been paramount in informing practice and generating policy while awaiting larger definitive trials. Trials such as RECOVERY in the United Kingdom, have begun to release results, including the finding of significant mortality benefit with dexamethasone among inpatients requiring oxygen or mechanical ventilation [4].

Despite the high-quality evidence being published to date, there has been a proliferation and publication of studies that have been scientifically inadequate. These studies have had outsized effects by leading to mass confusion and uneven policy development. Shortly after a French group published an uncontrolled study that suffered from major methodologic flaws [5] on the effectiveness of hydroxychloroquine and azithromycin, President Donald Trump touted hydroxychloroquine as a potential “game-changer,”
the Food and Drug Administration authorized emergency use, and widespread off-label use [6] caused global supply chain shortages, thus exposing individuals to risk and simultaneously threatening the health of people who take these medications for proven indications such as systemic lupus erythematosus. Without evidence of efficacy, the Indian Council of Medical Research recommended pre-exposure prophylactic hydroxychloroquine to the scores of health care workers in that country who may provide care for someone with COVID-19 [7].

Even high-impact medical journals have included studies that do not meet the most basic standards of scientific publishing. The Lancet recently published a large observational study of over 10,000 individuals taking hydroxychloroquine or chloroquine that showed no significant benefit, with an increase in mortality seen in this group compared to over 80,000 patients who did not receive these drugs [8]. The downstream effects of this study included a hold on the hydroxychloroquine arm of the World Health Organization Solidarity Trial, as well as appeals on the use of the drug in France. However, as scientists took a closer look at this publication, it became evident that there were significant concerns about the validity and veracity of the data [9]. In fact, close attention was also turned toward a study using the same registry that had been published in the New England Journal of Medicine three weeks earlier. It soon became evident that the data could not be verified, and both articles were retracted [10,11]. Annals of Internal Medicine published an experiment in which four COVID-19 patients coughed into a petri dish with and without cotton and surgical masks; the study reported that masks did not effectively reduce SARS-CoV-2 emission [12]. However, the authors failed to appreciate that the quantities in all cases were below the assay’s limit of detection, and thus the results were uninterpretable. The study has since been retracted [13]. These articles, despite their low quality of evidence and lack of context to the findings, lead to significant questions surrounding the transmission dynamics, pathophysiology, and management of COVID-19.

Rewinding to a century ago, syphilis was a significant cause of morbidity and mortality across the old and new worlds. The emergence of treatment strategies in syphilis, which were uncontrolled and extremely toxic, holds a unique position in medical history. A study published in JAMA in 1903 noted with regard to mercury-based therapy that

This knowledge, though purely empirical, has been so clearly and conclusively established, by centuries of observation and study, that it has become one of the most evident and acceptable of medical facts [ … ] (14 p1626)

Further research on arsenic-based therapy and therapeutic hyperthermia – achieved by infecting patients with malaria – also became medical standards and even worthy of the Nobel Prize. These therapies were offered to patients of all ages and degrees of infection based on a collection of anecdotes and uncontrolled studies.

Today, we look back on these studies with a sense of incredulity, as the advent and maturation of evidenced-based medicine have reframed the type and quality of studies that should be accepted for changing clinical practice. Yet, over the course of this pandemic, the evidence base upon which recommendations for unproven treatments are predicated is reminiscent of the standards of a century ago. Why are we repeating the mistakes of a century ago? Dealing with a threat with high stakes and no proven treatment is akin to being thrust back into the pre-antibiotic era, where desperation reigns. Long after our medical predecessors resorted to heavy metals or iatrogenic malaria for treating syphilis, we are now disregarding the hard-won principles of evidence-based medicine – at our peril. It is imperative that clinical decisions and public health policy remain grounded in the fundamental hierarchy of scientific evidence with the prioritization of well-designed studies, including appropriate controls.

What is the way forward? With an emerging disease, there may be a rush to treat with unproven therapies for the sake of offering patients something rather than just providing supportive care. In some settings, where a treatment is very obviously needed to change morbidity and mortality (such as the use of antimicrobials for bacterial sepsis), it would be unethical to complete a placebo randomized controlled trial. In the case of COVID-19, there is clearly clinical equipoise in a number of treatment modalities. The mandate of research institutions and academic centres should be to encourage the creation and/or synthesis of the best possible evidence. In the context of COVID-19, this should mean prioritization of generating high-quality randomized, controlled evidence wherever possible. Clinicians should provide excellent supportive care rather than prescribing experimental therapies (with unknown benefits and potential harms) outside of clinical trials.

CALL FOR PAPERS

The Canadian Journal of Infection Control is a leading international peer-reviewed journal providing a platform for knowledge transfer and academic discourse in the field of infection prevention and control and hospital epidemiology. The journal invites submission of manuscripts outlining original research that examines, informs, and advances this professional field.

Authors should follow the content and format recommendations as outlined in the journal’s Guidelines for Authors (https://ipac-canada.org/canadian-journal-of-infection-control-3.php). Manuscripts are accepted in English and French and should be submitted electronically by emailing all materials to the attention of:

Jim Ayukekong, Editor-in-Chief
Canadian Journal of Infection Control
editor-in-chief@ipac-canada.org

A signed copy of IPAC Canada’s Publisher-Author agreement must be received before a manuscript will be published. The agreement is available at https://ipac-canada.org/canadian-journal-of-infection-control-3.php.

Please note that there is an approximate three- to four-month timeline between receipt of manuscript, peer review, editing, and publication. The Canadian Journal of Infection Control is a quarterly publication indexed by the Cumulative Index to Nursing and Allied Health Literature (CINAHL)/EBSCO, SilverPlatter Information, Inc. and CrossRef.

CBIC proudly celebrates all IPs throughout the year especially during International Infection Prevention Week

**NO MORE CURTAINS!**

*2 easy and important facts to consider* when replacing privacy curtains with screens

---

**1. Easy Clean**

Optimises infection prevention

The Silentia Screen System meets strict hygiene requirements.

- All surfaces are smooth and easy to reach and disinfect
- All surfaces withstand disinfectants used in today’s care situations
- The wheels can be removed and machine washed
- Can be cleaned immediately unlike curtains. Faster room turnaround.

---

**2. Easy Return**

Quick and easy to fold back

Lightweight material and a Built In Memory for an easy and quick return to its original position.

The One Touch Point Handle means:

- No need for hands to touch other surfaces when folding the screen
- Only one hand needs to be used which reduces cross-infection

---

Contact us for a free demonstration.

Together we will help you find the right solution for your healthcare environment.
**Bacteria/Virus Contact Time**

- Staphylococcus aureus (ATCC 6538) 5 minutes
- Pseudomonas aeruginosa (ATCC 15442) 5 minutes
- Human Coronavirus 2 minutes
- Adenovirus Type 5 3 minutes

---

**BRINGING SCIENCE TO THE ART OF CLEANING**

**Coming soon**

PCS 1000 Plus Oxidizing Disinfectant Cleaner
- Oxidizing cleaner
- Oxidizing hospital grade Disinfectant
- Oxidizing broad spectrum virucide
- Active Ingredient 0.13% w/w Sodium Hypochlorite when packed
- Active Ingredient 0.01% w/w Hypochlorous Acid when packed

PCS 1000 Plus Oxidizing Disinfectant Cleaner for use on hard non-porous environmental surfaces in domestic, health care facilities, institutions, schools and hospitality industries.

To clean and oxidize frequently touched surfaces Apply undiluted to surface wipe dry with microfiber or other clean dry absorbent cloth or rinse or allow to air dry.

To disinfect frequently touched surfaces such as non-critical medical equipment, bed rails, washroom fixtures and surfaces that are potential fomites in health care facilities, long term care, schools, institutions and in domestic settings.

Apply to pre cleaned surfaces allow surface to remain wet for time indicated below. Wipe surface dry, rinse or allow to air dry.

This product is a broad-spectrum virucidal hard surface disinfectant that is expected to inactivate the SARS-CoV-2 (the virus that causes COVID-19)

Available in ready to use and concentrate formats.
Your hygiene is our #1 priority.

The first and only wipe that sanitizes and protects for 24 hours even after dozens of touches\(^1\)

Reach out or visit kcprofessional.ca

\(^{1}\) Kills SARS-CoV-2 Virus on hard, non-porous surfaces when used according to directions for use for disinfection. 
\(^{1}\) When used as directed, this product is effective for 24 hours against Enterobacter aerogenes, Staphylococcus aureus, and Community-associated Methicillin-Resistant Staphylococcus Aureus bacteria.

**KILLS the virus that causes COVID-19**

**WINNER of the 2021 WOW WORLD OF WIPES® INNOVATION AWARD**
With Sani Marc you can count on a trusted partner in Canadian healthcare

Our team of chemists, microbiologists and technicians developed SABER® disinfectant and X-PURE™ hand sanitizer in our laboratory. Both products are trusted in Canadian healthcare, and offer easy and accessible procurement.

SABER® is on the list of hard surface disinfectants proven for use against COVID-19 authorized by Health Canada and X-PURE™ is on the list of hand sanitizers (COVID-19) authorized by Health Canada to kill harmful bacteria and germs.

Infection Prevention and Control: Level 1 Certificate Course

In Person and Online delivery options available

This 90 hour course offers an up to date, comprehensive and evidence based introduction to basic Infection Prevention and Control (IP&C) Principles. Our experienced instructors use a combination of theory, practical application and facilitated discussion to stimulate and challenge students across the healthcare continuum. This entry level course is geared towards individuals new to IP&C including novice Infection Control Professionals, nurses, Public Health Inspectors, Medical Lab Technologists, Epidemiologists & health care professionals. The course also addresses Hot Topics at the forefront of IP&C including:

- Continuous Quality Improvement
- Screening for Antibiotic Resistance Organisms
- Patient Safety and Risk Management
- Prevention of Healthcare Acquired Infections
- Antibiotic Stewardship
- Healthcare Design

New courses, Practicum placements for graduates
